On a social network, study whether early debunkin...

Expected macro behavior: A single rumor wave peaks and then declines as believers recover; early debunking reduces or delays the peak.

Agents have skeptical thresholds — they reject the rumor after enough counter-exposures, and debunking is triggered when the rumor exceeds a prevalence threshold.

Expected macro behavior: Early debunking has little effect because most of the population is already recovered; early debunking flattens the curve substantially.

Scale-free network with influential hubs; rumor and debunking compete for the same susceptible population with asymmetric transmission rates.

Expected macro behavior: Network structure (hub vs. dispersed) strongly modulates debunking effectiveness — hubs accelerate both rumor and debunking.

Expected macro behavior: Early debunking inoculates a critical mass before the rumor reaches them, substantially lowering the peak.

Designed to compare debunking at multiple starting times to identify the critical window where intervention is most effective.
